

Do Foreign Gifts Buy Corporate Political Action? Evidence from the Saudi Crude Discount Program *

Jennifer R. Peck[†]

April 2017

Abstract

Between 1991 and 2003, Saudi Aramco sold crude to U.S. refineries at a substantial discount, with a total cost of approximately 8.5 billion dollars. This paper assesses the incidence of these discount rents in the U.S. market and yields the first empirical evidence for the use of oil as a tool of political leverage through transfers to American firms. Using panel variation in discount receipts, I find that rents were captured by refiners as profits and did not pass through into retail gasoline prices. Discounts were also associated with increases in refiners' political donations and strategic reallocations of these contributions.

1 Introduction

Political and economic concerns are fundamentally linked in the world petroleum market. Access to a dependable oil supply is critical to economic and political stability, and these supplies rely on local political climates. Oil is used as a political tool by suppliers, and is a frequent topic of diplomatic intervention. At the center of this is Saudi Aramco, the world's largest producer of crude oil and holder of 25 percent of global reserves. Because of its position as a global swing producer, the economic and political drivers of its output decisions attract a great deal of attention.

In addition to deciding how much to produce, Saudi Arabia also chooses where to sell its crude, a decision which receives much less attention but which is perhaps no less strategic. From 1991 to 2003, Saudi Arabia maintained a position as the top supplier of foreign crude to U.S. refiners in order to support its political alliance with the United States. Although oil is often thought of as having one world price, Saudi Aramco supported this export strategy by selling the same crude at different prices in different geographic markets. Maintaining the pricing differentials required by its export targets appears to have been both politically strategic and quite expensive: between 1991 and 2003, Saudi Arabia spent approximately 8.5 billion dollars selling discounted crude to the United States. The per-barrel discount relative to the Asian price reached a high of 6.30 dollars, 30 percent of the U.S. crude price in 2001, and was worth 1.9 billion dollars that year alone. In achieving its export target, Saudi Arabia therefore transferred substantial rents to the U.S. oil industry in the form of discounted crude supplies. In addition to determining the total value of this transfer through its export quotas and pricing policies, Saudi Arabia also controlled how these rents were distributed within the United States; discounted crude was targeted at specific refineries using highly restrictive sales contracts.

Despite the magnitude of this transfer and the fact that these prices are publicly available, the Saudi crude discount program has received almost no attention in the academic literature or in the popular press.¹ In this paper I first document the size of these rents and identify the refiners that received this gift. I then evaluate the success of this allocation mechanism as a political tool by identifying where rents accrued as a result of the policy and how these rents were related to political action by discount recipients. To do this, I first estimate the effect of discounts on refinery-owner

¹Despite considerable attention to Saudi Arabia's petroleum production and exports, *The Quest* – Daniel Yergin's history of the world energy market post 1991 – never mentions this program.

profits and local gasoline prices. I then examine the effect of discount receipts on one particular type of measurable corporate political action: contributions to congressional campaigns. The analysis follows the money from the original oil shipment to the campaign funds of federal politicians.

The analysis relies on several key features of the market for Saudi crude in the United States. All U.S. refiners pay the same per-barrel price for Saudi crude each month, but quantities differ both across refineries and within a single refinery from month to month. These quantities are based on long-term contracts, but are subject to unilateral changes by Saudi Aramco each month. This yields variation in the total value of the discount to each refinery, which in turn creates variation in discount receipts across refining companies and in the geographical distribution of discounted crude. It is therefore possible to estimate the effect of the discount on company-level outcomes (profits and political contributions) and market-level prices for refined products.

There are several main results. First, there was a great deal of heterogeneity in the value of the discount received by different companies and significant geographical dispersion in the destination of Saudi crude. Even among refineries of similar capacity and in similar locations There is also variation even among refineries of similar capacity and in similar locations as well as within a single refinery over time.

This variation allows for an estimation of the impact of discount receipts both on refiner profits and gasoline prices in local markets. Correspondingly, the second result is that most of the discount rents were captured by refinery owners as profits rather than passed through to consumers as lower gasoline prices. This is to be expected given that the discount was targeted only at certain refineries, so the effect on market-level costs tended to be infra-marginal. The capture of rents appears to have been almost complete, supporting the idea that the discount was purposefully targeted at specific refiners. Finally, I find that discount receipts were related to refining company political contributions, with recipients targeting more of their financial support to politicians on committees that considered bills of interest to Saudi Arabia. I also find that funds tended to be diverted away from politicians who received donations from pro-Israel interest groups.

These results tie together several different areas of study. First, although the Asian price premium (or, U.S. discount) for Saudi crude has attracted occasional comment in the trade press on petroleum markets, it has received very little attention in the academic energy literature. Exceptions are several papers that have attempted to explain the premium in terms of models of

price discrimination or regulatory distortions. Soligo & Jaffe [2000] model Saudi Aramco's pricing decision as that of a dominant firm operating in two fully separated markets and assert that Asian/European price ratio is consistent with reasonable values of supply and demand elasticities and Saudi market shares. In a response, Parsons & Brown [2003] propose an alternative model of international oil markets as a Cournot duopoly, with Gulf OPEC producers competing in both markets with local suppliers. Horsnell [1997] argues that government involvement in Asian procurement has been at least partially responsible for the higher prices Asian firms pay for oil.² This study adds to this literature by showing that these price differentials created rents for U.S. refiners, suggesting that the differentials were larger than those predicted by competitive conditions in the two markets.

This paper also provides evidence on the incidence of non-marginal cost changes in the oil refining industry. Borenstein & Kellogg [2014] examine the effect of a similar change in average input costs caused by the oil glut in the U.S. Midwest beginning in early 2011. They also find that the relative decrease in local crude oil prices did not pass through into wholesale gasoline and diesel prices, and conclude that refiners must have received the rents generated by the crude price shock. This paper complements their analysis by examining a setting with richer variation in cost changes and showing that not only was the cost decrease not passed through into prices, but that it was instead captured by refiners as profits rather than by retailers or other market intermediaries.

This paper also adds a quantitative dimension to the literature on the political economy of global energy markets, providing empirical evidence for the use of Saudi oil not only directly as a tool of political leverage, but through transfers to American companies. The political motivations behind Saudi supply patterns have been previously examined from a historical perspective, notably by Moran [1981] and more recently in a comprehensive history by Jaffe & Elass [2007]. Moran [1981] argues that OPEC behavior is best understood by looking at the political motivations of Saudi Arabia between 1973 and 1980. In an unpublished working paper, Jaffe & Elass [2007] similarly argue that Saudi Aramco's behavior has often been guided by the kingdom's foreign policy goals; they outline the kingdom's policy of maintaining a position as the top global supplier of crude to the United States beginning in 1990, and provide a historical survey that follows the eroding

²Other papers have discussed strategies for Asian consuming nations to reduce or eliminate the premium through regulatory reform [Ogawa 2003] or by improving pipeline infrastructure [Jaffe & Soligo 2004].

relationship between the two countries and subsequent policy reversal in 2003.

This analysis further adds to the broader literature on the relationship between business and politics and the determinants of political giving by corporations. There is a long literature suggesting that campaign contributions may be a key way for companies to engage in rent-seeking, including Pittman [1977] and Krueger [1974]. Empirical work by Fisman [2001], Jayachandran [2006], and Shon [2010], for example, indicates that these political connections can be valuable to firms. There is also some evidence on what determines political giving and how firms decide how much to contribute and how to allocate donations. Notably, recent work by Holland, Hughes, Knittel, & Parker [2014] finds that firms may allocate campaign contributions to support their regulatory interests. There is also evidence that political donations are a consumption good for executives, with contributions increasing in executive pay [Ansolabehere, de Figueiredo & Snyder 2003] and correlated with agency problems within the firm [Aggarwal, Meschke & Wang 2012]. This paper adds to this literature by providing new evidence on how these preferences are formed. In particular, the Saudi crude discount program is a non-standard lobbying channel that offers a window into how firm preferences over the amount and allocation of their political giving are affected by their other business relationships.

The rest of the paper proceeds as follows. Section 2 gives some background on U.S.-Saudi relations, and Section 3 describes the history of the discount policy and how Saudi Aramco targeted 3 the discount rents. Section 4 provides evidence on who captured these rents, and Section 5 discusses how discount receipts were related to political action by U.S. oil refiners.

2 Background: Oil Policy in U.S.-Saudi Relations

2.1 Aramco Before Nationalization

The discount policy, which began in the 1990s, was part of a longstanding linkage between American oil companies and Saudi political interests. This dynamic began in the 1930s, with the simultaneous foundation of Saudi Arabia and its oil concession to an American company. The next sixty years saw the evolution of a complex relationship of political and economic connections between the Saudi government, a consortium of American oil companies, and the U.S. government. Saudi Arabia often used its oil to influence U.S. policy, with American oil companies acting as its

willing conduits and active partners.

From the beginning, American oil companies were directly involved in U.S.-Saudi relations. Indeed, the founding of Saudi Arabia and its subsequent recognition by the U.S. in 1933 coincided with the discovery of oil by Standard Oil of California (SoCal) in the region. Aramco, a joint venture between SoCal (now Chevron) and Texaco, was established in 1944 following the discovery of several major oil fields in Saudi Arabia. Mobil and Exxon joined the consortium several years later. The U.S. government gave special status to this company in order to bolster its alliance with Saudi Arabia, sharing half of the U.S. tax revenue from the consortium with the Saudi government [Yergin 1991, 447]. By the Arab-Israeli wars of the 1960s and 1970s, the company had become both a source of leverage for the United States as well as a representative of Saudi foreign policy toward the U.S. In 1967, oil minister Sheikh Yamani warned the U.S. government of the “consequences” of giving aid or support to Israel, sending his message through Aramco for emphasis [Brown 1999, 268]. The American partners themselves also advocated for Saudi interests in the U.S., particularly in regard to the Arab-Israeli hostilities of the 1960s and 1970s. This included reaching out to State Department contacts following the outbreak of the Yom Kippur War in May 1973 [Sampson 1975, 292-293], and advocating for the Saudi political agenda in the popular press.³⁴ That July, SoCal’s chairman sent out his own letter to the company’s employees and shareholders asking them to pressure their representatives to “acknowledge the legitimate interests of all the peoples of the Middle East” and encourage Washington to improve relations with Arab governments [Sampson 1975, 294]. On October 12, six days after the start of the Yom Kippur War, the chairmen of Exxon, Texaco, Mobil and SoCal sent a joint memo to President Nixon’s chief of staff warning that U.S. aid to Israeli forces would result in “a critical and adverse effect on our relations with the moderate

³On June 21, 1973, Mobil published an “advertorial” in the *New York Times* calling on the U.S. government to join with the Soviet Union in insisting on a peace agreement in the Middle East. The article argued that continued American prosperity depended on U.S. support of Saudi interests in the Middle East, and warned that “political considerations may become the critical element in Saudi Arabia’s decisions, because we need the oil more than Saudi Arabia will need the money” (*New York Times*, 1973). Oil minister Yamani later wrote to Mobil’s president praising the ad and calling it a “positive step”.

⁴In a particularly bizarre incident, Mobil Oil took out another full-page ad in the *New York Times* on May 8, 1980 regarding a documentary called “Death of a Princess” that was set to air on PBS two days later. The film told the story of a young Saudi princess who had been publicly executed for committing adultery. It was considered extremely unflattering by the Saudi regime, and Mobil (which was one of the major supporters of PBS) called on the network to cancel the broadcast. The last line of the article read:

“We hope that the management of the Public Broadcasting Service will review its decision to run this film and exercise responsible judgment in the light of what is in the best interest of the United States.” (*New York Times*, 1980).

Arab producing countries” and the loss of American influence in the region “to the detriment of both our economy and our security” [Sampson 1975, 300]. Indeed, the oil embargo began five days later on October 17th, and Aramco was compelled to enforce the Saudi boycott of oil sales to the United States and other Israeli supporters to maintain its concession.

In 1981, American oil companies again inserted themselves in the middle of Saudi-U.S. diplomacy preceding the controversial sale of the AWACS (Airborne Warning and Control System) surveillance planes.⁵ Once again, the oil industry launched an extensive political campaign in support of Saudi Arabia. Mobil in particular spent more than half a million dollars on full-page advertorials in the *New York Times*, again emphasizing the importance of the economic partnership between Saudi Arabia and the United States. Mobil’s president also personally called Arkansas senator David Pryor to lobby for the sale [Bard 2010]. Congress eventually approved the landmark sale, despite strong opposition.

Although American interests continued to manage the company during the 1980s, the Saudi government began to take a more active role in setting oil policy. In 1986, oil minister Yamani had been charged by the king to both increase Saudi oil production and increase the world oil price. Yamani attempted to balance these two mandates using a policy that would be a precursor to the discount scheme, offering some customers a secret 50 cent-per-barrel discount on their contract price to try to meet the production quotas. The discount caused overall oil prices to fall and spurred tensions with other OPEC members, and the King relieved the previously highly successful oil minister of his post. Nonetheless, this action announced the King’s intention to control oil policy more directly rather than working through OPEC (*New York Times* 1986, *PIW* 1986, *Financial Times* 1986, Adelman 1995, Jaffe & Elass 2007).

After nearly sixty years of Saudi-U.S. partnership, control of Aramco passed fully to the Saudi government in 1990. Even without its American partners, the newly-independent Saudi Aramco would continue in its role as a critical conduit for diplomatic relations between Saudi Arabia and the United States.

⁵James Atkins, former Ambassador to Saudi Arabia, predicted that Saudi Aramco would keep the crude price at 32 dollars if the AWACS sale was allowed to proceed [Adelman 1993].

2.2 Diplomacy After Nationalization: “Oil for Security”

Just as the American-owned Aramco served as an intermediary for American and Saudi interests through the 1980s, Saudi Aramco has continued to work to achieve the kingdom’s foreign policy goals since nationalization. While the company’s core mission is to maximize oil profits, this goal is often superseded by the government’s foreign policy agenda. The most significant examples of this are the use of Saudi Arabia’s considerable excess production capacity to stabilize U.S. oil supplies and the U.S. export quota policy.

Saudi Aramco has used its excess capacity at key moments to serve U.S. economic interests during oil supply emergencies. The first such incident occurred just after full nationalization in 1990, when Iraqi forces invaded Kuwait at the start of the first Gulf War. As promised, American forces were immediately deployed to Saudi Arabia, and President Bush requested that the kingdom immediately increase production in order to replace lost U.S. crude supplies from Iraq and Kuwait. Within three months the company had raised production by 2 million barrels per day (bpd) to 7.3 million bpd. The oil price, which had surged to 40 dollars per barrel on the news of the invasion and UN boycott, fell immediately back to pre-invasion levels [Jaffe & Elass 2007]. Another notable instance of this strategic export expansion occurred in 2002, when Saudi Aramco pledged to replace U.S. supplies lost during the Venezuelan oil strike. In return for this type of strategic assistance, the United States provided the Saudis with domestic intelligence, protection against external threats, and advanced weaponry. The American commitment to protect the Gulf states was first explicitly stated in 1980 in President Carter’s State of the Union and later reiterated by President Reagan, who specifically articulated a commitment to intervene to protect Saudi Arabia in particular. This commitment was borne out most clearly at the beginning of the Gulf War, when American forces arrived in Saudi Arabia less than two weeks after the invasion of Kuwait.

In addition to its own security, Saudi Arabia has also used its oil as a tool of influence in the Israeli-Palestinian peace process. Indeed, the most overt use of Saudi oil as a political tool occurred before 1990, with the threatened expropriation of Aramco in 1967 and the oil embargo of 1973, both of which occurred in response to American support of Israeli military actions. Since then, Saudi advocacy has focused mostly on U.S. diplomacy toward Israel, actively soliciting American support for a Saudi peace plan in 2002. Despite repeated diplomatic pressure from Saudi Arabia, however,

the United States failed to pressure Israel to accept the plan and U.S.-Saudi relations continued to deteriorate. This deterioration in diplomatic relations coincided with the abandonment of the discount policy in 2003.

3 The Discount Policy

3.1 History

The discount policy began in 1990 as a politically-motivated export quota policy. Following Aramco's full nationalization and transition to Saudi control, King Fahd directed the company to maintain a position as the top supplier of foreign crude to the United States [Jaffe & Elass 2007]. The stated purpose of this policy was to cement Saudi Arabia's strategic alliance with the United States by making itself critical to U.S. energy security. Achieving the quota on a month-to-month basis was initially quite straightforward; Aramco supplied as much as a third of total U.S. imports in the early 1990s while keeping the U.S. price for Saudi crude roughly the same as the world price. By the end of the decade, however, increasing competition from Mexico, Venezuela and Canada forced Aramco to cut its U.S. prices to defend its market share (Figure B.2). The discount reached a high of \$6.30 per barrel in 2001, 30 percent of the U.S. selling price at the time (Figure I). The total nominal value of the discount over the policy period from 1991-2003 was 8.5 billion dollars.

As the discount became larger, the Saudi government faced increasing pressure from Aramco to abandon the expensive quota policy.⁶ These increasing costs were coupled with increasing skepticism about the policy's benefits after a string of political disappointments in the early 2000s. The Kingdom had strongly disapproved of American intervention in Iraq in 2003, and tensions increased after the 9/11 Commission Report described alleged Saudi links with the hijackers and funding sources from within the Saudi government. President Bush declined to support King Abdullah's peace plan in the escalating Arab-Israeli conflict.

The policy was suspended in 2003, with Aramco allowing the average discount to fall to zero and ceding the top exporter spot to Canada. Saudi crude exports, which had averaged 15.9 percent of total gross imports in the first half of 2003, fell to 13.1 percent in the second half of the year and

⁶For more details see Jaffe & Elass [2007].

then to 11 percent in the beginning of 2004. Industry observers noted the apparent policy change⁷, and Saudi Aramco President Abdullah Jumah publicly acknowledged the shift in February 2005⁸.

3.2 Discount Distribution

The prices that refiners pay for Saudi crude deliveries are determined by Aramco's Official Selling Prices, or OSPs. Aramco's OSP announcement is made a month before delivery, and consists of a differential relative to the spot price of a different benchmark crude for each of the four markets. Over the policy period, these benchmark crudes were West Texas Intermediate (WTI) for the United States, dated Brent for Europe and the Mediterranean, and the Oman-Dubai average (ODA) for Asia. These differentials reflect factors such as the quality differences between the marker crude and the Saudi crudes and product prices in different markets. The price that refiners pay is calculated using the previously announced differential and the average price of the marker crude over the month.

For example, the January 2002 differentials for Arab Light to the United States and Asia were -4.05 and +0.25, respectively. During January, the average WTI price was 19.48 dollars per barrel, and the average spot prices of the Oman and Dubai crude markers was 18.34 dollars per barrel. The price paid by U.S. refiners for January deliveries of Arab Light was $19.48 - 4.05 = 15.43$ dollars per barrel, and the price for Asian refiners was $18.34 + 0.25 = 18.59$ dollars per barrel. The value of the "discount" that month was therefore the difference between the realized Asian and U.S. prices, i.e. $18.59 - 15.43 = 3.16$.

In addition to setting the prices that refiners pay, Saudi Aramco also directly controls how much crude each refinery receives each month. Saudi Aramco only sells crude through long-term contracts with specific refineries, and does not permit resale. Although many petroleum producers trade their crude on a spot basis and/or allow their crude to be traded by buyers ex post, Saudi Aramco does neither and keeps tight control over where its crude is processed. Any resale by refiners results in permanent blacklisting from future contracts, and even companies that refine Saudi crude

⁷ "Has Saudi Arabia abandoned its pivotal policy of being the largest crude supplier to the U.S.? The world's top oil exporter has long had the biggest share of the world's largest oil market and has favored volume over price to retain the top spot. Intriguingly, since the spring of last year, in the wake of the U.S.-led invasion of Iraq, the Saudis have ceded their prime position to others." ("Saudis Drop Volume, Lose U.S. Top Spot" *Petroleum Intelligence Weekly*, May 12, 2004.)

⁸ Jad Mouawad and Simon Romero, "Saudis in Strategy to Export More Oil to India and China," *The New York Times*. February 18, 2005.

in multiple locations must specify the particular refinery where they will process each shipment. Contract quantities are specific to refinery capacity to process Saudi crude, and potential buyers submit detailed contract applications that provide refinery specifications and operating figures. Once approved, these contracts may then be renewed on an annual basis at the discretion of the refinery and Saudi Aramco.

Despite the rigidity of the contract rules for refiners, the actual delivered quantities vary significantly from month to month. While annual contracts specify the quantity that refiners are willing to buy in terms of barrels per day, deliveries are subject to unilateral cuts by Aramco. Quantities may be cut, for example, following a decrease in OPEC quotas or a mandate from the Saudi government.⁹ Indeed, there is significant monthly variation in the quantities that buyers receive each month, both at the refinery and company level. Although Aramco frequently changes quantity deliveries, it is very unusual for refiners to cut their orders even when prices are high.¹⁰ Refinery inputs are constrained by physical capital in the short run, and most refineries require the composition of their input blend to be fairly consistent. Refiners can replace a shortage of Saudi crude by buying a fairly close substitute or higher-grade crude on the spot market, but these prices are usually higher than the Saudi term contract prices. Aramco also tries to keep its contract terms fairly attractive on average so that customers want to renew their contracts over the long term and so that they can continue to place their desired quantities in the U.S. market.

4 Where Did the Discount Go?

The first task of this paper is to track down where discount rents accrued when Saudi Aramco sold discounted crude to the United States, whether captured by refiners as excess profits or passed on to consumers in the form of lower product prices. I next provide an overview of the relevant features of the U.S. refining industry and give some intuition on the likely incidence of the discount.

⁹In practice Saudi Aramco does allow buyers to switch between the several crude grades it produces or to ask for a change in the total quantity. In the month prior to delivery, Saudi Aramco announces its price differentials, customers then indicate their preferences, and Saudi Aramco considers these requests when issuing the final allocation.

¹⁰“Despite their grumbling, customers - sensitive to the strategic importance of Saudi contracts - will not dare threaten to reject their March supplies. ‘We can only hope that we’re compensated next month with a deep discount on the April formula,’ says an industry source. . . . One US contract holder, none too pleased with the March price adjustment, carefully described the change as ‘very inconsistent with the market.’ Again, however, loyalty to Aramco seems certain to win out over momentary irritation. ‘We are painfully aware of the new prices, but we’re dealing with it,’ the customer added.” *Petroleum Intelligence Weekly*, “Buyers Bemoan Saudi Price Hikes, Eyes Now on Iraq” (Feb. 8, 1999).

I then discuss the data required for this part of the analysis, the empirical framework, and the results from the estimation.

4.1 Market Details

A refinery’s main function is to distill input crude oil into its constituent hydrocarbons, isolating the molecules and then blending them into end products like propane, gasoline, jet fuel and diesel. Although all refineries perform this same basic process, they vary significantly in what sorts of crude oil they can process and what finished products they output. The simplest refineries include only distillation units and produce mainly unfinished oils. More complex refineries add hydrotreating and cracking or coking units to remove sulfur from sour crudes and break larger (and less valuable) molecules into lighter, more valuable products. The product mix is determined both by the blend of molecules in the input crude mix as well as the sophistication of the refinery.

Most refineries blend different crude oils before distillation begins. This allows them to maintain consistent processing conditions and mitigate the corrosive effects of cheaper sour crudes. Most refiners secure a certain amount of “baseload” crude under term contracts, which are less flexible but offer more attractive prices, and then balance their remaining crude slate in the spot markets. If a refinery gets a cut in its monthly crude order from Saudi Aramco it will buy similar or higher-quality crudes on the spot market to fill the shortfall rather than curtailing their run. Spot market prices for these inputs are usually higher than Saudi term contract prices, however, so replacing a shortfall of Saudi crude on the spot market tends to increase input costs. Because Saudi crude is delivered to the U.S. by ship, refiners have several months to secure a replacement crude once they receive notification of a cut in their delivery.

Once the crude oil has been fully processed, refined products are transported to wholesale racks by either pipeline, barge, truck or rarely by railroad [Association of Oil Pipelines 2009]. Pipelines are the least expensive way to move products,¹¹ and mainly connect areas of high refining output with those of high demand. Trucks usually make only local trips, and most trips by petroleum tank trucks are no longer than 50 miles [Untiet 1984]. Refiners sell products to retailers out of these local wholesale racks, who then mark up the prices to sell to consumers. These retail margins make

¹¹Transportation costs by pipeline, barge and truck are estimated at 2, 4.5 and 35 cents per gallon per thousand miles of transportation [Jacobs 2002].

up only a small proportion (about ten percent) of consumer prices.

The two primary possible destinations for Saudi discount rents are therefore refiner profits and consumer prices.

4.2 Framework

Although changes in crude oil costs certainly influence the consumer price of gasoline, there is reason to think that discounts targeted at specific refineries will be captured as profits rather than passed on to consumers, even in a competitive market. The structure of the product market and the nature of the discount means that discount-related cost shocks are likely to be non-marginal, passing through into refiner products rather than consumer prices. This is a likely consequence of capacity constraints in refining and heterogeneity in Saudi crude receipts across refineries.

Over the policy period, Saudi oil accounted for about ten percent of crude refined in the United States, and crude receipt varied substantially across refineries in the same local area. The receipt of Saudi crude can therefore be thought of as a heterogeneous cost shock across refineries in a given market. Each gasoline wholesale market is characterized by a relatively small number of refineries with fixed capacities. Most refineries operate at full capacity for most of the year, and even with regular shutdowns for maintenance overall capacity utilization is around 90 percent. Though fixed costs are large, the majority of marginal costs are the price of crude inputs. These vary across time as the price of crude fluctuates, and across refineries according to refinery sophistication.

While common shocks to costs do pass through into gasoline prices, cost shocks targeted to specific refineries will tend to affect profits but not prices. In a wholesale market with a finite number of refineries with fixed short-run capacities the product price will be determined by the marginal firm's profit maximization facing the residual demand from all lower-cost firms producing at capacity. Therefore non-marginal shocks to marginal cost will only affect refiner profits and will not pass through into prices. Decreasing the costs of the marginal firm will lower prices, increase profits of the marginal firm and lower profits for other firms.¹² Consequently, in this environment we would expect most receipts of discounted crude to affect refiner profits and not to pass through into product prices. Since most refiners are inframarginal, most of the discounted crude is also

¹²See Figure II for a simple example of how a common shock to costs (such as a change in the world price of crude) would affect both profits and prices, but a targeted decrease in costs to inframarginal refineries (such as the discount) would affect profits but not product prices.

inframarginal; only changes in the amount of Saudi crude sold to the one marginal producer in each market would even partially be passed through into the price. This reasoning is similar to that of Borenstein & Kellogg [2014], who find that refiners, not consumers, captured the rents generated by a temporary depression in crude prices in the Midwest. Their model similarly predicts this lack of pass-through into product prices as a consequence of the fact that most refiners are capacity-constrained, and are therefore operating at the vertical part of their supply curves.

4.3 Data

In this part of the analysis, I follow the discount through each stage of the refining process from the delivery of the discounted crude to the refinery to local gasoline prices.

4.3.1 Total Discount Value

The key independent variable for the analysis in this paper is the refinery-level value of the discount received from Saudi Aramco, i.e. the per-barrel discount multiplied by the quantity of crude delivered to each refinery. I calculate the per-barrel discount that U.S. refiners receive relative to Asian refiners using Saudi Aramco’s official selling prices. The OSP releases are published each month by Platts for each of the major crude grades in each market, and the realized selling prices (these differentials plus the relevant benchmark) are available from Bloomberg. The series for Arabian Light, Arabian Medium, and Arabian Heavy are available for Europe, the United States, and Asia beginning in January 1991, and I use these series to construct a single average discount for Saudi crude.¹³ I use the difference between the U.S. price and the Asian price to approximate the discount for several reasons. First, East Asia was the primary alternative destination for Saudi crude exports. Asian markets received about half of total Saudi crude exports by 2003 and 65 percent by 2010. At the same time, the share that went to the North American market fell from what had been a steady 25 percent from 1991 to 2003 down to 18 percent in 2010 (UN Comtrade). Additionally, the differential against the Asian price returned to zero once the discount policy was

¹³Since only overall sales volumes for all the crude types are available, I calculate the discount as a weighted average of the discounts on the three different crude grades. The weights are left fixed over time and are based on the volumes published in the IEA Oil Market Report over the 1998-2003 period. The average discount is calculated as

$$AvgDiscount_t = 0.35 \cdot LightDiscount_t + 0.46 \cdot MediumDiscount_t + 0.19 \cdot HeavyDiscount_t.$$

abandoned in 2004, supporting the idea that the Asian and U.S. prices for Saudi oil would likely have been the same in the absence of the policy. For these reasons, the U.S.-Asian price differential represents a meaningful approximation of both the cost to Aramco of pursuing the policy as well as the benefits to U.S. refiners.¹⁴

Monthly data on Saudi crude receipts come from the Energy Information Administration (EIA) in the EIA-814 Monthly Imports Report. I match this data to a list of all operating refineries in each year constructed using the EIA Refinery Capacity Report (EIA-820), which lists all operating U.S. refineries in each year for 1994, 1995, 1997, and 1999-2010 and reports capacity, owner, and state for each refinery.

Receipts vary a great deal across refineries and within each refinery from month to month, which leads to considerable variation in discount values among refinery owners and across states. Of the 178 operating refineries, 58 used crude imported from Saudi Arabia between 1991 and 2003. Most deliveries of Saudi crude go to refineries along the Gulf Coast, but a surprising amount also goes to inland refineries and to refineries in California and along the East Coast (Figure III). Coastal refineries are mostly supplied by tanker and offshore terminal, and inland refineries receive deliveries by pipeline within a couple of weeks of delivery by tanker.¹⁵

4.3.2 Refiner Profits

To estimate the impact of the Saudi crude discount on refiner profits, I use data on annual profits from refining operations for the 40 publicly-traded companies that owned at least one U.S. refinery during the sample period. These data come from Standard and Poor's Compustat North America dataset. The analysis focuses on refining operating profits, which represents sales of the refining business segment less its allocated share of operating costs and expenses.

I identify refinery ownership using the EIA Refinery Capacity Reports supplemented with corporate profiles from the Moody's/Mergent Industrial Manuals. Refineries owned through a joint enterprise were assigned to either the U.S.-listed corporation or to the majority stakeholder.¹⁶ Re-

¹⁴The main results are also robust to using the European price rather than the Asian price as a benchmark to approximate the discount value.

¹⁵There is also a great deal of variation in the fraction of inputs that come from Saudi Arabia. The Texaco refinery in Delaware, for example, got more than half of its inputs from Saudi Arabia over the period. Mississippi and Arkansas also got over half of their crude inputs from Saudi Arabia (Figure B.4).

¹⁶Texaco is an exception to this, and is excluded from the regressions due to its Motiva joint venture with Saudi Aramco. In general, including Texaco in the regressions either has no effect or slightly decreases point estimates and

fineries that changed ownership mid-year were assigned to the company that owned the refinery for the majority of the year.¹⁷ Discount receipts for these companies also vary tremendously and are not necessarily related to company size. Chevron and Texaco, for example, received over 4 billion dollars worth of crude discounts, an amount equal to 10% of their overall refining profits. The similarly-sized Shell, however, received only 0.08 billion in discounted crude, 0.2% of total refining profits. Smaller companies like Marathon and Valero received about a billion dollars in discounts over the period as well. On a yearly basis the value of discount receipts relative to profits could also be quite large: in 2001, Valero received 0.25 billion in discounted crude, an amount equivalent to a quarter of its total refining profits that year. Although a substantial share of the discounted crude went to the former Aramco partners (ExxonMobil, Chevron and Texaco), other companies like BP, ConocoPhillips, Marathon and Valero were also top recipients. There is also great deal of variation in the fraction of inputs that come from Saudi Arabia. Texaco, for example, received Saudi imports at seven of its ten refineries and devoted approximately 45 percent of its processing capacity to refining Saudi crude.

4.3.3 Retail Gasoline Prices

In addition to examining the effect of the discount on refining profits, I also look at the impact on consumers through changes in the retail price of gasoline in local refinery markets. For this part of the analysis, refineries were matched to the largest city within an hour travel time by road. Monthly city-level retail price averages for regular unleaded gasoline for the 75 cities with local refineries was obtained from the Oil Price Information Service (OPIS).

I link this price data for each city to refining capacity and Saudi crude quantities in its wholesale market. I define a city's market in two different ways. In the first, local markets are defined using the assumption that refineries serve only cities within an hour travel time by truck. I alternatively define a refinery's market as any city that is "down-pipe" of the refinery using directional product pipeline information from 2004 (Figure B.6).¹⁸ Under the first definition, for example, retail prices in St. Paul and Chicago are assumed to be affected only by the refineries operating in their local

increases their statistical significance.

¹⁷Table B.1 provides some summary statistics on the publicly-traded refinery owner companies that appear in the profits analysis.

¹⁸This is similar in spirit to Muehlegger [2006], who also uses product pipelines (as well as truck and barge access) to calculate the approximate transportation costs for a refinery to serve markets in each state.

area. The second market definition takes into account that there is a product pipeline going from Bismarck to St. Paul, and from St. Paul to Chicago. Prices in Bismarck are still only affected by refineries in the local area, but St. Paul prices are now also affected by refineries in Bismarck as well as in St. Paul, and prices in Chicago by refineries in Bismarck and St. Paul.

4.4 Empirical Framework and Results

In this section I estimate the effect of discount receipts on refinery owner profits and local retail gasoline prices to determine whether the discount was captured as profits or passed through to consumers.

4.4.1 Refining Profits

To determine the extent to which the discount was captured as profits, I estimate the relationship between company-level refining profits and total annual discount value as well as the relationship between log profits and log quantity:

$$\pi_{jt} = \beta \cdot DiscValue_{jt} + \alpha_j + \gamma_t + \epsilon_{jt} \quad (1)$$

$$\log(\pi_{jt}) = \tilde{\beta} \cdot \log(q_{jt}^{saudi}) + \tilde{\alpha}_j + \tilde{\gamma}_t + \tilde{\epsilon}_{jt} \quad (2)$$

The motivation for these two specifications comes from the expression for the refiner’s profits. The value of the discount to a refiner can be expressed in terms of the percentage discount on the crude price (d_t), the per-barrel price of crude (c_t), and the number of barrels the refiner receives from Saudi Arabia in year t , q_{jt}^{saudi} . We can then write the refiner’s profit function:

$$\begin{aligned} \pi_{jt} &= (p_t - c_t)q_j^{cap} + \beta \cdot DiscValue_{jt} + \epsilon_{jt} \\ &= \mu_t q_j^{cap} + \beta \cdot d_t \cdot c_t \cdot q_{jt}^{saudi} + \epsilon_{jt} \end{aligned}$$

where p_t is the average product price and q_j^{cap} is refinery capacity. μ_t is the difference between the average product price and the cost of crude, i.e. the refining profits per barrel or the “crack spread”.

In this case, β can be consistently estimated using firm fixed-effects as long as μ_t is fixed over

time and does not vary with the crude price, i.e. $\mu_t = \mu$. Indeed the crack spread was relatively stable from 1983-2003, remaining fairly constant in real terms at around 12 dollars per barrel (Figure B.5). This leaves us with:

$$\pi_{jt} = \underbrace{\mu q_j^{cap}}_{\alpha_j} + \beta \cdot DiscValue_{jt} + \epsilon_{jt} \quad (3)$$

A more serious empirical problem is created by integrated refiners. Since these firms also sell crude, the crude price now enters the calculation for the discount value as well as the profitability of their exploration and production business lines:

$$\pi_{jt} = \mu \cdot q_j^{cap} + \beta \cdot \underbrace{d_t \cdot c_t \cdot q_{jt}^{saudi}}_{DiscValue_{jt}} + \underbrace{c_t \cdot q_j^{crude}}_{\eta_{jt}} + \epsilon_{jt}$$

Now $Cov(DiscValue_{jt}, \eta_{jt}) > 0$, and $\hat{\beta}$ overestimates the effect of the discount on refiner profits. Intuitively, the discount per barrel can only be large when the price of crude is also large – you cannot have a six-dollar discount when the crude price is only five dollars. We would also expect refiners that produce crude to have higher profits when the oil price is higher. Even though I use refining profits in this analysis to try to mitigate this effect, these self-reported segment profits are likely to co-move with overall company profits.

One solution to this problem is to use a log-log specification and add time fixed effects to remove time-varying factors (c_t, d_t) from the discount. The coefficient $\tilde{\beta}$ now estimates the percent change in profits associated with an increase in the quantity of Saudi crude that a refiner receives.

$$\log \pi_{jt} = \tilde{\beta} \cdot \log(q_{jt}^{saudi}) + \tilde{\alpha}_j + \tilde{\gamma}_t + \tilde{\epsilon}_{jt} \quad (4)$$

Since the discount per barrel is mostly positive over this period, a positive estimate indicates that an increase in the total discount value to a refiner is associated with an increase in firm profits.

Results from the profit regressions (Table I) indicate that most of the discount appears to be captured by refiners as profits. On average, the discount value is equal to about two percent of refining profits, and the average discount is one dollar per barrel over the period. Full capture would therefore be consistent with a coefficient of 0.02 in column 1. The actual point estimate is

0.016, i.e. a 1.6 percent increase in profits associated with doubling the amount of Saudi crude delivered.¹⁹ When the sample is restricted only to observations with non-zero amounts of Saudi crude and positive profits, the point estimate increases to 0.17 relative to the full pass-through benchmark of 0.09 for this subsample.

The point estimate from the level regression in column 3 is large, implying a three dollar increase in profits for every dollar of discount, and may be biased upward for the reasons discussed in the previous section.²⁰ Nonetheless, the test of this coefficient against the full pass-through benchmark of 1 cannot be rejected. Controlling for refiner size (as captured by refining capacity) does not affect the main results in these regressions or in the gasoline price regressions in the next section.

To support the interpretation that the receipt of discounted crude increases profits through reducing costs rather than by increasing output, I also estimate the effect of annual Saudi crude receipts on total refinery output using capacity utilization rates available at the refining district level. Because events like refinery shutdowns and capacity expansions are likely to affect both production levels and inputs, I control for total district refining capacity. I use time fixed effects to capture trends in capacity utilization rates and district fixed effects to control for district-level heterogeneity in refinery efficiency.

Table II reports the results from this regression of the log of production on Saudi crude receipts controlling for refining capacity and year and district fixed effects. These estimates are all very small; a doubling in the Saudi crude delivery is associated with around a 0.3 percent increase in production even though about ten percent of crude inputs came from Saudi Arabia. This is in contrast to the estimate in column (1) of Table II, which indicates a 1.6 percent increase in profits for the same increase in Saudi crude quantity. The primary channel for the impact of the receipt of discounted crude on profits is therefore the discount on costs rather than an increase in production.

¹⁹This may be an under-estimate of the effect on profits if firms smoothed reported refining profits from year to year.

²⁰Consistent with the hypothesis that the upward bias of the estimate in the level regression is due to measurement error due to other business lines, the point estimate in column 3 decreases to 2.48 when I exclude the supermajors (BP, ExxonMobil, Chevron and Shell), which had the largest incomes from crude production. The estimates in columns 1 and 2 decrease slightly but remain statistically significant.

4.4.2 Retail Gasoline Price

I also examine the extent to which the discount was passed through to consumers by estimating the effect of the city-level discount per gallon of refined gasoline and quantity share in production on local gasoline prices:

$$\begin{aligned} RetailPrice_{mt} &= \rho \cdot DiscGal_{mt} + \lambda_m + \eta_{st} + \epsilon_{mt} \\ \log(RetailPrice_{mt}) &= \tilde{\rho} \cdot \log\left(\frac{q_{mt}^{saudi}}{q_{mt}^{cap}}\right) + \tilde{\lambda}_m + \tilde{\eta}_{st} + \tilde{\epsilon}_{mt} \end{aligned}$$

The retail gasoline price can be expressed as a per gallon markup on the crude costs per barrel (p_t^g) plus some state-level tax τ_{st} . The observed price is this counterfactual price (η_{st}) plus the effect of the discount, which is expressed here as the discount value per gallon of gasoline refining capacity multiplied by ρ , the share of the discount which is passed on to consumers. This yields:

$$RetailPrice_{mt} = \underbrace{p_t^g + \tau_{st}}_{\eta_{st}} + \rho \cdot DiscGal_{mt} + \epsilon_{mt} \quad (5)$$

Using the constant crack spread μ , p_t^g can be expressed as a markup μ over the price of crude c_t divided by the number of gallons of gasoline per barrel:

$$p_t^g = \frac{\mu + c_t}{19.5}$$

where 19.5 is the average number of gallons of gasoline refined from a 42 gallon barrel of crude oil. The discount per gallon is calculated as the total discount to refineries in market m divided by the total number of gallons of gasoline refined in that market:

$$DiscGal_{mt} = \frac{d_t c_t q_{mt}^{saudi}}{q_m^{cap}}$$

As discussed earlier, one of the primary challenges here is defining the local market in order to link refineries to the appropriate retail gasoline prices. I do this two ways: first by assuming that refineries only serve cities within an hour travel by truck, and second by linking each refinery to all cities “down-pipe” of the refinery. These two definitions affect how q_{mt}^{saudi} and q_m^{cap} are calculated.

Under the first definition, they refer to Saudi imports and refinery capacity only in refineries within an hour’s travel from the city. Under the second, they refer to imports and capacity of all refineries up-pipe.

Again, taking logs and using state by month fixed effects removes any bias caused by the crude price appearing in both the counterfactual gasoline price and the value of the discount.

$$\log(DiscGal_{mt}) = \underbrace{\log(d_t c_t)}_{\gamma_t} + \log(q_{mt}^{saudi}) - \underbrace{\log(q_m^{cap})}_{\lambda_m}$$

The primary specification is therefore

$$\log(RetailPrice_{mt}) = \tilde{\rho} \log\left(\frac{q_{mt}^{saudi}}{q_m^{cap}}\right) + \tilde{\lambda}_m + \tilde{\eta}_{st} + \tilde{\epsilon}_{mt} \quad (6)$$

The pass-through coefficient $\tilde{\rho}$ is therefore identified off of variation in the changes in Saudi crude shares across cities within the same state.

The results show no evidence that discounts were passed on consumers in the form of lower refined product prices (Table III). Estimates in column 1 give fairly precise zeros (with standard errors clustered at the city as well as the state by year and month level), even when compared with a full pass-through benchmark of -0.04²¹. The full pass-through benchmark for cities that receive positive amounts of Saudi crude (column 2) is -0.15, so these estimates are also very close to zero. Large standard errors on the estimates in column 3 make their interpretation more difficult, but the point estimates are nonetheless quite small. Panel A of column 3, for example, indicates that a one-cent increase in the per-gallon discount value decreases gasoline prices by 0.03 cents. These estimates are consistent with the large pass-through into refining profits in Table I.

Taken together, the profits and retail price results indicate that, as expected, the discount rents were captured by refining firms as profits rather than passed on to consumers. Since refining companies appear to have been the primary beneficiaries of the discount, the next section examines how discount receipts were related to political action by these firms.

²¹The average unleaded gasoline price is 1.34 dollars, and Saudi inputs make up about 5.5 percent of total inputs, so a one percent increase in the Saudi input share would decrease prices by 0.04 percent.

5 Political Action by Discount Recipients

While it is impossible to directly measure the effect that the discount actually had on U.S. foreign policy toward Saudi Arabia, we can observe how the companies that received the discount behaved as a result of the policy. As described earlier in the paper, there are many cases where American oil companies took (sometimes rather extraordinary) political action to support Saudi interests. The most easily measurable type of corporate political action is financial contributions to political campaigns. In this section, I examine the relationship between discount receipts and political contributions by American refiners during the policy period. I focus on refiner contributions to members of Congress, particularly those who serve on key committees and those who appear to be most sympathetic to Israeli political interests. The advantage of focusing on individual donations is that it shows the direct link from refiners to politicians so that patterns of giving can be examined in addition to overall levels of giving. Patterns that are seen in this small, transparent part of political action by discount recipients may be suggestive of overall patterns of behavior as it relates to the receipt of the crude discount.

5.1 Saudi Arabia and the U.S. Congress

There is a large amount of work in the public choice literature that suggests that campaign contributions may be a key way for companies to engage in rent-seeking.²² This is particularly likely to happen in industries where the potential benefits are concentrated among a small number of players, as they are in the refining industry. However, the empirical results in the literature on political contributions and policy influence are mixed. In particular it has proven relatively difficult to show direct causal links between contributions and voting behavior, though there is some evidence that regulatory outcomes are influenced by political contributions (see e.g. [de Figueiredo & Edwards 2007] and [Gokcekus, Adams, Grabowski & Tower 2006]).²³ In their study of the incidence of the costs and benefits of several transportation-sector environmental regulations, Holland et al. [2014] find patterns in the political donations by organizations and politician voting behavior that suggest that districts used campaign contributions to influence the House vote on the Waxman-

²²See for example [Pittman 1977] and Krueger [1974].

²³There is still an open debate over whether politicians are influenced by contributors, or whether contributors simply support the candidates who are known to favor their interests. See for example Bronars & Lott [1997] for some evidence of the latter explanation.

Markey cap and trade bill. Lopez [2001] similarly finds evidence that campaign contributions from agricultural PACs are associated with more advantageous agricultural subsidies. As discussed by Ansolabehere et al. [2003], campaign contributions may affect policies in other ways besides through roll call votes, including securing access to legislators at other stages of the policy-making process. Indeed, politicians likely find it desirable to promote client interests in ways that are observable to clients but not to voters. Because of these difficulties in observability, I assume that corporate donors allocate their donations strategically, whether with the intent of affecting policy or to demonstrate support for Saudi interests.

In particular, contributions to federal legislators are an important channel corporations can use to advocate for Saudi interests. Many bills pass through Congress that affect Saudi Arabia, including bills regarding arms sales, trade, aid, and visas for Saudi visitors. Examples of aid-related bills include H.R.3137.IH (2003) which prohibited assistance or reparations to Cuba, Libya, North Korea, Iran, Syria and Saudi Arabia, as well as Amendment 708 to H.R. 4818 (the Foreign Operations Appropriations bill for FY2005). Most of these are referred to the House Committee on Foreign Affairs or the Senate Committee on Foreign Relations. Committees exercise a great deal of power over the legislation they review, and can both block legislation by tabling it or by revising the bill before they send it to the floor for a vote. In 1992, for example, none of the bills opposing the sale of F-15XP fighter planes to Saudi Arabia made it out of committee. In another example, the House Foreign Affairs Committee tabled the Persian Gulf Security Cost Sharing Act (2001), which would have required Saudi Arabia to defray the cost of U.S. military deployments in the region.

Committees can also amend popular bills to turn them from aggressive foreign policy changes into purely symbolic gestures. The House Committee on Foreign Affairs had added Presidential waiver authority to several anti-Saudi bills, including the Anti Economic Discrimination Act of 1995, which would have stopped the sale of military equipment to countries participating in the boycott of Israel. Another notable example of this was an amendment to the 2005 Foreign Appropriations bill, which stated that “[n]one of the funds appropriated or otherwise made available pursuant to this act shall be obligated or expended to finance any assistance to Saudi Arabia.” Changes to this amendment made in committee allowed the President to waive this rule provided that he certified to the Congressional Appropriations committees that Saudi Arabia was cooperating in the war

against terrorism. Although the amendment passed,²⁴ it was immediately waived by Presidential Determination. A subsequent bill (the Prohibit Aid to Saudi Arabia Act of 2005) that attempted to impose the ban on U.S. aid to Saudi Arabia without waiver authority was not passed on by the House Foreign Affairs Committee.²⁵

The rest of the paper examines how the level and composition of direct corporate donations to Members of Congress vary with discount receipts.

5.2 Data

In this part of the analysis, I match company-level discount receipts to corporate political donations. Although it is illegal for corporations to contribute to political campaigns directly, contributions may come through personal donations by their managers and employees. These individual donors account for approximately two-thirds of campaign money to Senate candidates and half of the financing for House candidates. The FEC publishes the name, address, occupation and employer of donors for all contributions over 200 dollars. I use these data to construct total annual campaign contributions by employees of all U.S. refining companies to each member of the House and Senate for the 1991-2003 period. I merge these with data on congressional committee assignments from Stewart & Woon [2012] and Nelson [2012] to construct total contributions by committee.²⁶ The positive relationship between Saudi imports and total political contributions over the period can be seen graphically in Figure IV, which plots the log of total company campaign contributions against the log of total Saudi imports over the discount policy period controlling for refining profits.

For the politician-level contributions analysis, committee assignments and political contributions are matched to the set of all Members of Congress collected in Stewart & Woon [2012], which begins in 1993. The merged politician by refiner-level dataset contains information on politician characteristics including party affiliation, committee assignments, chamber seniority, and contributions from other types of interest groups. The analysis classifies politicians according to the degree

²⁴Vote 217-191, see roll call <http://clerk.house.gov/evs/2004/roll389.xml>

²⁵In practice the United States provides almost no aid to Saudi Arabia, and the ban targeted a small 25,000 dollar International Military Education and Training grant for Saudi military training.

²⁶Table B.2 shows some summary statistics on political contributions for the 26 companies that received crude from Saudi Aramco, both public and private. Though companies that received no Saudi crude are excluded from this table, all 126 refining companies are used in the analysis.

to which they receive contributions from donors affiliated with pro-Israel groups. One categorization simply assigns a dummy variable equal to one for politicians who received any contributions from pro-Israel donors. Another categorizes politicians according to their approximate quintile of average pro-Israel donations. The first group is the approximately 27 percent of politicians who never received any contributions from pro-Israel organizations during their time in Congress. The second group collects the 27th through 40th percentile of recipients, the third the 40th through 60th percentile, the fourth the 60th through 80th percentile, and the fifth the 80th percentile and above.²⁷ The median contribution to a single politician is only around one thousand dollars per year, though the maximum contribution is very high; in 1996, Koch Industries affiliates and employees contributed almost 45,000 dollars to Representative Sam Brownback’s (R-KS) campaign. The median total giving by a company in a single year is 7,404 dollars, but again the maximum is quite high; ExxonMobil made over 374,000 dollars in direct contributions in 2000.

5.3 Results

5.3.1 Contribution Aggregates

As in the profits analysis, I estimate the relationship between discounts and political contributions using the regression

$$Contrib_{jt} = \theta \cdot DiscValue_{jt} + \alpha_j + \gamma_t + \epsilon_{jt} \quad (7)$$

where j is the contributing refining company and t is the year. One possible concern here is the effect of refiner profits on contributions. If corporations increase overall contributions or change their contribution patterns when their profits are high, θ may capture the spurious common effect of overall crude price on contributions (via profits) and the discount value or the indirect effect of the discount through its effect on profits. I therefore also run this regression on a the subsample of public companies (for which I have refining profits) both with and without profit controls.

Results for the aggregate contribution regressions are reported in Table IV. The top panel shows the results for the whole sample of refiners (both public and private). Column 1 shows the

²⁷Table B.3 gives some summary statistics for the total annual contributions at the company by politician level. Since most politician-refinery-year observations are zeros, the left hand panel shows statistics conditional on a donation occurring.

relationship between discount receipts and total donations, and Columns 2 and 3 break this out into aggregates for contributions to politicians and to PACs. The estimate in Panel A of Column 1 indicates a small but positive relationship between the discount and overall political contribution by refiners – a one-million dollar increase in the discount value is associated with an approximately 385 dollar increase in contributions. This is consistent with the fact that contribution magnitudes tend to be much smaller than the discount value. Among discount recipients, the average discount amount is 45 million dollars per year and often varied substantially from year to year; the average annual fluctuation in the value of the discount was 25 million dollars. The average discount, then, is associated with a contributions increase of 17,325 dollars, which is quite substantial compared with the annual company average of 18,578 dollars from Table B.3. Positive and significant estimates of the elasticity of contributions with respect to discount receipts in Panel B confirm this relationship. The lower panels display the same results for the subsample of corporations that report profits data. The results are consistent with the estimates for the full sample, though the point estimates tend to be larger. Controlling for profits has almost no effect on the estimates for this subsample, which is reassuring for the full sample results.²⁸

Interestingly, these estimates are close to previous estimates of the relationship between corporate profits and political contributions. Jayachandran [2006] finds that for every dollar companies had donated to the Republican party, firms lost 2,313 dollars of their market value following the shift of control in the U.S. Senate when Senator Jim Jeffords switched his party affiliation from Republican to Democrat in May 2001. This estimate implies that a one million dollar decrease in market value would have been associated with a contribution of 432 dollars to the Republican party. My estimates of the effect of discount receipts on overall political giving indicate an increase of 385 dollars in response to the receipt of one million dollars in discounted crude. Ansolabehere et al. [2003] find that top corporate executives increased their personal giving to congressional campaigns by 510 dollars for every additional million dollars of income per year.

I also consider the direct effect of profits on contributions by comparing the effect of the discount with that of non-discount profit shocks. To capture non discount-related variation in refiner profits, I use hurricane landfall events as an instrument for annual profits. Hurricanes affect oil

²⁸When the same specification is run for the post-policy period (2004-2011), the point estimate on the relationship between discount receipts and political contributions is negative and not statistically significant.

and petroleum product production in several ways. As a hurricane approaches the coast, offshore platforms are evacuated and wellheads are plugged to prevent leakage. These offshore platforms are sometimes destroyed by hurricanes, which imposes direct costs on producers and disrupts oil supplies. In addition to shutting down upstream crude, hurricanes also affect downstream infrastructure. Underwater pipelines can be damaged, and ports may stop accepting shipments. Onshore refineries can also be heavily damaged; Hurricane Rita, for example, caused refining capacity losses of more than 4.9 million bpd due to direct damage or power interruptions along the Texas coast [EIA 2006].²⁹

I construct the hurricane instrument using a dummy variable equal to 1 if a company had a refinery in a state that was hit by a hurricane in that year. This is further split into dummy variables for each hurricane category – i.e. dummy variables indicating the most severe hurricane level experienced by a refinery owned by company j in year t . I focus on the most damaging hurricanes, i.e. those that were classified as category 2, 3, or 4 on the Saffir-Simpson scale [Simpson & Saffir 1974], with sustained surface wind speeds of 82-95 knots, 96-112 knots, and 113-136 knots, respectively.³⁰ I then use these hurricane indicators to instrument for profits in a regression of political contributions on refining profits and discount receipts.³¹

$$(FS) \quad Profits_{jt} = \delta \cdot DiscValue_{jt} + \zeta_1 \cdot \mathbb{1}(\text{Category } 2)_{jt} + \zeta_2 \cdot \mathbb{1}(\text{Category } 3^+)_{jt} + \alpha_j + \gamma_t + \epsilon_{jt}$$

$$\widehat{Profits}_{jt}^{hurr} = \hat{\zeta}_1 \cdot \mathbb{1}(\text{Category } 2)_{jt} + \hat{\zeta}_2 \cdot \mathbb{1}(\text{Category } 3^+)_{jt}$$

$$(SS) \quad Contrib_{jt} = \beta_1 \cdot DiscValue_{jt} + \beta_2 \cdot \widehat{Profits}_{jt}^{hurr} + \alpha_j + \gamma_t + \nu_{jt} \quad (8)$$

I then test $\beta_1 > \beta_2$ to determine whether discount receipts had a larger effect than other types of profits. Table V reports the results for the regression of total contributions on discount value and profits orthogonal to the discount. Panel A reports results from the first stage regression, which confirm that discounts increase profits and hurricanes decrease them, and that the hurricane

²⁹Other papers have examined the effect of hurricanes and tropical storms on U.S. refined product markets, including Fink, Fink & Russell [2010], Kaiser, Dismukes & Yu [2009] and Lewis [2009].

³⁰There are five relevant hurricane landfall events in the sample. Hurricane landfall and severity data comes from NOAA [2006].

³¹Allowing for more flexibility in the effects of hurricane landfall events on profits has little impact on the results. In particular, indicators for refineries owned in adjacent states were statistically insignificant in the first stage and had no effect on the two-stage least squares results.

instruments and the discount have comparable explanatory power for profits. The results in panel B show that only discount receipts seem to have an effect on total contributions, with a one million dollar increase in the discount associated with a 317 dollar increase in contributions (column 1). Column 2 shows the corresponding elasticity estimate, and a ten percent increase in the discount is associated with a 3 percent increase in political contributions. Profits not associated with the discount have no statistically significant effect on contributions, and the point estimates are close to zero as well. In both regressions we can reject the hypothesis that discount receipts and orthogonal profit shocks have the same effect on contributions.

The second set of results (Table VI) shows the relationship between the discount value and the way that total contributions were allocated among various committees. For the foreign policy committees, for example, the regression is of the share of congressional contributions that go to members of the House or Senate foreign policy committees.

$$Share_{jt}^{FP} = \frac{Contrib_{jt}^{FP}}{Contrib_{jt}^{total}} = \theta \cdot DiscValue_{jt} + \alpha_j + \gamma_t + \epsilon_{jt} \quad (9)$$

Though the standard errors on these estimates are large, the pattern is suggestive. The coefficient on contributions to the foreign policy committees is not statistically significant, but there is a substantial increase in contributions to members of the Appropriations committees, which also review Saudi-relevant legislation. The coefficient in Column 2 indicates that a one billion dollar increase in the discount is associated with a 39 percentage point increase in the share of contributions that go to Appropriations committee members. The average discount of 45 million dollars would therefore correspond to a 1.8 percentage point increase in contributions to members of the Appropriations committees. This is about seven percent of the average share of 27 percent. I also include some results for “placebo” committees, that would be less likely to be concerned with Saudi affairs. Most of these coefficients are either zero or negative and significant.³²

It is not possible to draw conclusions about the direction of causality from this analysis, and both contributions and discount are certainly the product of a complex relationship between Saudi Aramco and U.S. refiners. Nonetheless, we can examine the time structure of the relationship between contributions and discounts by running regression (7) for lags and leads of contributions

³²As in Table III, most of these results remain the same when I control for profits, though the further loss of observations increases the standard errors.

on company-level discount value in year t . Figure V summarizes the results from these regressions, with the timing of contributions relative to discounts on the x-axis and the separate point estimates of θ from these regressions on the y-axis. The largest statistical relationship is between discounts and contributions in the previous year, with a 951 USD increase in contributions in year $t - 1$ associated with a one million dollar increase in discounts in the following year.

5.3.2 Politician-Level Contributions

To further explore the effect of the discount on political giving, I also examine the effect of the discount on corporate contributions at the politician level. In this part of the analysis, company-year level discount receipts are interacted with a set of politician characteristics (g_i) to estimate how discount receipts affected contributions to different types of politicians. These politician characteristics include a dummy variable for receiving contributions from pro-Israel interest groups, quintiles of the level of pro-Israel contributions, party affiliation and committee membership:

$$Contrib_{ijt} = \theta \cdot g_i \cdot DiscValue_{jt} + X_{it}\beta + \alpha_{ij} + \gamma_t + \epsilon_{jt} \quad (10)$$

where i indicates the politician, j the company and t the year. Controls X_{it} are dummies for the time-varying politician characteristics (chamber seniority and committee membership).

In Table VII, we see that the discount tended to decrease giving to pro-Israel politicians, with a one billion dollar increase in discount receipts decreasing annual contributions by an additional 118 dollars to politicians who received pro-Israel funding (column 1). Column 2 shows this same result split up by quintile, and the point estimates indicate larger penalties for politicians in the higher pro-Israel funding quintiles associated with the discount. The pattern is similar in the regression with the full set of interactions. Republican politicians benefit more from the discount than Democrats and independents. Republican candidates get a 166 dollar boost from companies that received an additional billion dollar discount relative to Democrats and independents (column 3). Again, the pattern is the same in column 5, with Republicans taking a 152 dollar increase. The evidence on the committee membership patterns is much more mixed, and contrasts with the patterns in the aggregate contribution regressions. Point estimates on the committee membership interactions are very sensitive to controls, and are large and negative for the House Foreign Affairs

committee in both columns 4 and 5. Estimates for members of other committees are noisy, and although point estimates are quite large none are statistically significant.³³

In general, these results indicate significant politician-level heterogeneity in the impact of the discount on funding by refining companies. Top beneficiaries were Republicans and candidates who did not receive funding from pro-Israel groups. If Israeli interest groups donated more to candidates that were perceived as being pro-Israel, this could indicate that the discount caused refining companies to divert funds away from pro-Israel politicians, a move consistent with the Saudi political agenda toward the Arab-Israeli conflict.

It is notable that all of these estimates are quite small. The 118 dollar penalty to pro-Israel donation recipients, for example, implies that the average discount of 45 million dollars would be associated with just a five-dollar decrease in contributions to these candidates. From Table B.3, the average contribution to these candidates, however, is only 38 dollars, so the five-dollar increase is a reasonable proportion of the total, though difficult to think of as practically significant. Nonetheless, the pattern of the change in this type of contribution is likely suggestive of other political responses, both financial and otherwise, by discount recipients.

In addition to categorizing politicians by how much money they received from other interest groups, we can also examine how recipients voted on anti-Saudi legislation. As discussed earlier, most of the Saudi-relevant legislation introduced in congress over the period was stopped at the committee-level. A notable exception occurred at the end of the policy period, with Amendment 708 to H.R. 4818, the amendment to the FY2005 Foreign Appropriations bill prohibiting any spending on aid to Saudi Arabia. The controversial amendment was approved by the House on July 15, 2004 by a vote of 217-191, with 25 Members abstaining. Table VIII shows the results from an LPM regression of a dummy variable for whether a member of the House voted “No” on the amendment on contribution totals from different groups over the 1991-2003 period. Here “contributions by recipients” indicates the total amount of contributions received from refiners in years in which they received Saudi crude. “Contributions by non-recipients” are all contributions from refiners in years in which they did not receive Saudi crude.³⁴ There is evidence that contributions from discount

³³When the sample is restricted to years when the discount was large (1998-2003, Table B.4), the patterns become more clear for the pro-Israel and committee assignment results. In particular, the estimate of the discount penalty to pro-Israel donation recipients increases to 253 dollars, and a statistically significant pattern of larger penalties to politicians who received more pro-Israel money emerges (column 2).

³⁴The results are robust to changing these definitions so that “contributions by recipients” includes all contributions

recipients were associated with an increased likelihood of voting “No”, an increase of two percentage points for every million dollars of total contributions. Contributions from non-recipient refiners and from pro-Israel interest groups were associated with small but statistically significant decreases in the likelihood of voting against the amendment. The point estimates on the effect of contributions by recipients decrease to one percentage point per million dollars in contributions when controls for committee membership and political ideology are included. The impact of including the political ideology controls in these regressions and the importance of party affiliation in the allocation of funds indicates that contributions may be used both as a way to support known allies as well as to influence voting preferences.

6 Conclusion

This paper examines the relationship between the Saudi crude discount program and the political behavior of U.S. firms. This policy is an empirically appealing example of Saudi strategic political behavior both because it had a clearly measurable cost and because it was effectively directed at specific recipients. There are three main sets of results. First, I calculate that the program transferred substantial rents to the U.S. market, with a total discount value of 8.5 billion dollars over the policy period. Second, I find that the discounted crude was almost entirely a gift to refinery owners, with full pass-through of discount receipts into refiner profits. Finally, the results suggest that this gift was related to some amount of pro-Saudi political action on the part of recipients. In particular, I find that discount receipts were associated with higher levels of overall political giving and with an increase in the share of funds directed toward members of key congressional committees. On the politician level, there is also some evidence that recipients tended to divert funds away from congressmen who received donations from pro-Israel interest groups.

There are two possible explanations for this observed pattern in the data. First, the pro-Saudi shift in corporate political contributions could reflect a direct and intentional effort by Saudi Arabia to influence the U.S. political process. However, the pattern is also consistent with rent-seeking by firms trying to protect their future access to discounted crude. This behavior could reflect either a desire to be seen as friendly by Saudi Arabia, or simply efforts to protect the interests of a country

(in every year) from refiners that ever received discounted Saudi crude.

with which they had developed close economic ties. In any case, the results indicate that U.S. refiners responded to the discount, and that the policy successfully influenced their political action.

Figure I: Saudi Crude Quantity, Discount, and Discount Value

(a) Saudi Crude Deliveries to U.S. Refineries, mil bbl per month. Source: EIA-814

(b) Saudi Crude Discount to U.S. Refineries, $(p_{ASIA} - p_{US})$. Source: Platts

(c) Total Value of the Saudi Crude Discount, mil 2000 USD per month

Figure II: Common cost shocks affect both price and profits, but inframarginal shocks affect only profits.

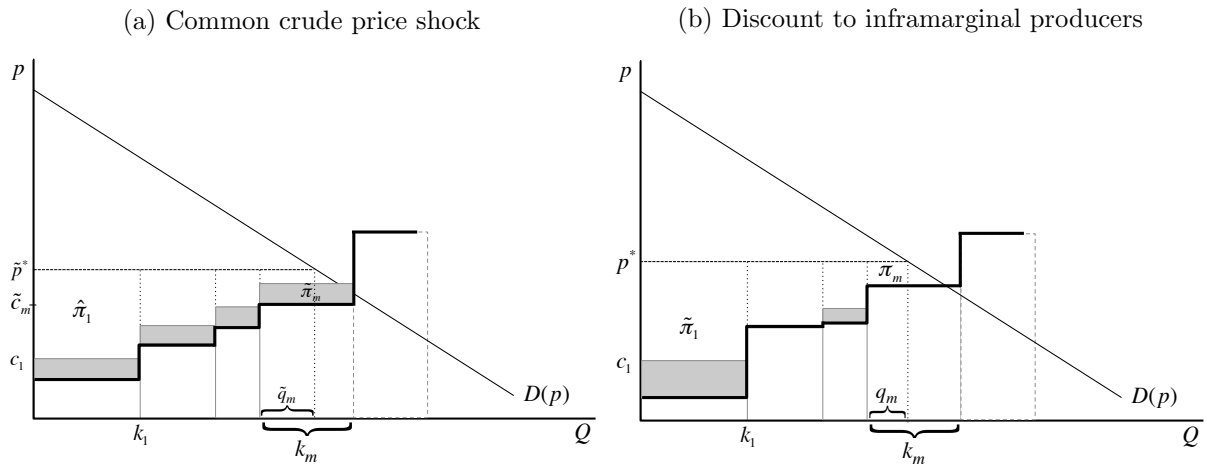

Figure III: Saudi crude quantity by refinery, mil bbl: 1991-2003

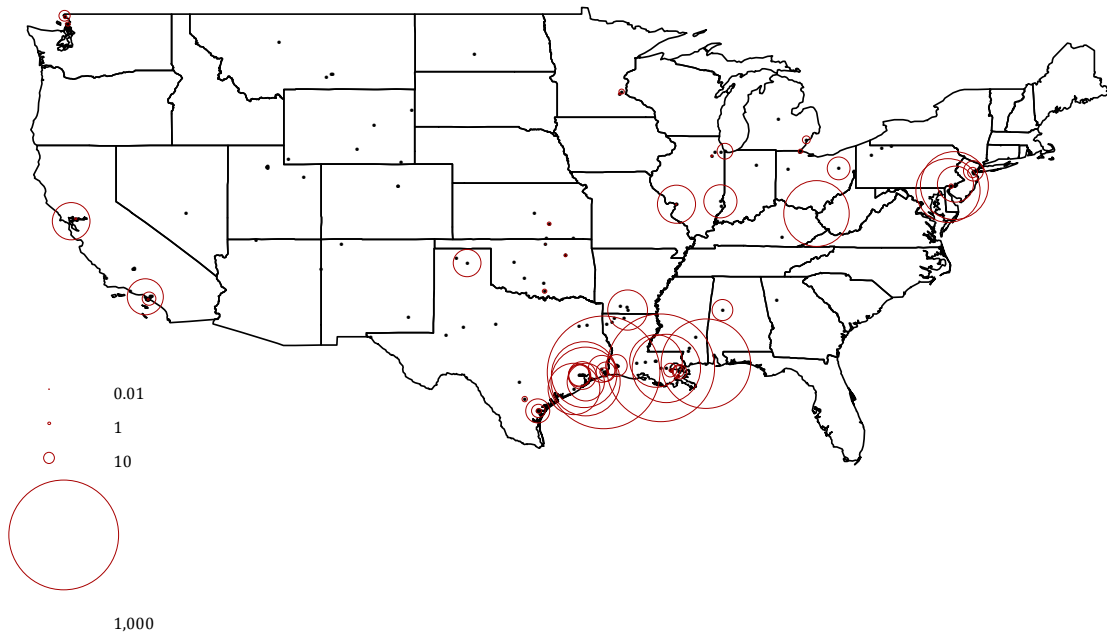

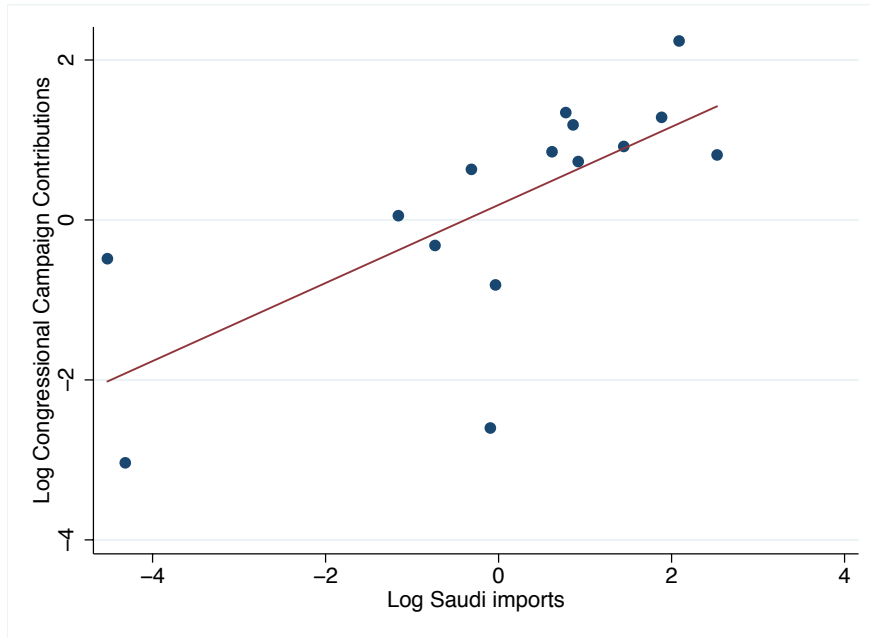

Figure IV: Correlation of Total Saudi Imports and Total Campaign Contributions by Company

Note: This figure plots the log of total congressional campaign contributions (mil USD) over the 1991-2003 period against the log of total Saudi imports (thousands of barrels) controlling for refining profits. Regression line is $\ln(\text{amount}) = 0.488 * \ln(\text{Saudi imports}) + .381 \ln(\text{Refining Profits}) - 0.543$; $F(2,12) = 17.30$.

Figure V: Time Structure of Correlations of Campaign Contributions with Discount Receipts

Note: This figure plots the coefficient on discount value from regressions of lags and leads of company-level campaign contributions on discount value in year t . Dashed lines represent the 90% confidence interval. All regressions include company and year fixed effects. Standard errors are clustered at the company level.

Tables

Table I: Impact of the Discount on Refining Profits

	Quantity: log (1)	Quantity: log (2)	Value: level (3)
Discount Value	0.016** (0.007)	0.169*** (0.045)	3.38** (1.56)
H ₀ : full pass-through (p-value)	0.620	0.101	0.135
Companies	39	16	39
N	317	81	317

Notes: Columns 1 and 2 report results from the regressions of log annual company-level refining profits on log quantity of Saudi crude delivered to refineries owned by the same company in that year for the 1991-2003 period. In the regression in Column 1, 1 is added to profits and 1 to quantity to avoid losing observations (both in billions) and column 2 drops observations with negative profit observations or zero Saudi quantities. Column 3 shows the results from a regression of the level of refining profits on total discount value. The second row reports the p-value of an F-test of the coefficient against the full pass-through benchmark of 0.02 for column 1, 0.09 for column 2 and 1 for column 3. All regressions include company and year fixed effects. Standard errors are clustered at the company level.

Notes: Results for LPM regression of a dummy for whether House member voted “No” on an amendment barring U.S. aid to Saudi Arabia on contribution totals from the 1991-2003 period. There were 217 “Aye” votes, 191 “No” votes, and 25 Members not voting. The House approved the amendment on July 15, 2004. Contribution totals include political donations from refiners in years in which they received Saudi crude, contributions from non-recipient refiners, and pro-Israel interest groups. Columns 2 and 4 include controls for committee membership. Columns 3 and 4 control for political preferences captured by two-dimensional DW-NOMINATE scores (Carroll et al. 2011). All contributions are in millions of 2000 USD.

*** p<0.01, ** p<0.05, * p<0.1

A Appendix: Who received the discount?

To get a sense of which features made companies most likely to receive Saudi crude, I first construct a dummy variable ($D(\textit{Recipient})$) equal to 1 if the company received Saudi crude at any point over the policy period. I estimate a simple descriptive linear probability model for this dummy variable on a set of refiner characteristics. These include total refining capacity over the period as well as a dummy variable indicating whether the company owned any refineries that had processed Saudi crude in the 1989/1990 period, indicating that the company had the technical capacity (without any further investment) to process crude from Saudi Arabia. I also construct a set of dummy variables that indicate whether the company owned a refinery in a particular state to get at geographical effects. Anticipating the results in section 5, I also include a set of variables indicating political contributions by these companies in the 1989/1990 period to check whether recipients differed from non-recipients in their political leanings.³⁵

The results from the LPM for discount receipt on refiner characteristics (Table A.1) reveal that the most important requirements to have received Saudi crude are technical. Companies that owned at least one refinery with demonstrated capacity to process Saudi crude were 65 percent more likely to have received Saudi crude over the policy period. Of course, the availability of substitute crude inputs means that these firms do not require Saudi crude, and that refineries that did not process Saudi crude in the pre-period may still have had the capacity to do so. Firms may also have updated refinery specifications during the period to enable Saudi crude capacity. Nonetheless, this variable is significant in all seven specifications and its magnitude is quite consistent. There is no indication that firms with larger overall refining capacity were more likely to receive Saudi crude, and these coefficients are close to zero and statistically insignificant. Former Aramco partners were surprisingly no more likely to get Saudi crude than other refiners controlling for technical refining capacity.

The coefficients for the state dummy variables are not reported in the table, and are jointly significant but mostly individually not statistically significant. These estimates tend to be positive for states that are easily accessible by barge (e.g. Alabama, Louisiana, California, New Jersey) and negative for those that are difficult to reach (e.g. Alaska, Arizona, Illinois, Nevada). (Including these dummy variables in the other LPM regressions has very little effect on the point estimates, but makes the standard errors on the other coefficients larger.)

The estimates on the aggregates for overall contributions, contributions to politicians and contributions to committees are all small and statistically insignificant. The aggregates by politician characteristics (party, pro-Israel donation recipients) are also very small and close to zero, indicating that the overall contribution patterns of recipients and non-recipients were very similar in the pre-period. Recipients and non-recipients do appear to have varied in how their contributions were allocated across members of various committees, however; companies with more contributions to members of the House Armed Services and Senate Foreign Relations committees were more likely to receive Saudi crude. Companies with more donations to members of the House Energy, House Foreign Affairs, and Senate Armed Services committees were less likely to get Saudi crude.

³⁵The political contributions data are discussed in detail in section 4.

Notes: Results for LPM regression of a dummy for whether a refining company received Saudi crude during the policy period on a set of refiner characteristics. These include whether the company ever owned a refinery that had processed Saudi crude in the pre-policy period (1989-1990), total refining capacity in billions, an indicator for the former Aramco partners, and pre-period political contributions to Members of Congress by party affiliation and committee membership. All political contributions are in thousands of 2000 USD. State dummies indicate whether a company owned any refineries in a particular state.

Figure B.4: State-level Saudi inputs as a share of total refining capacity

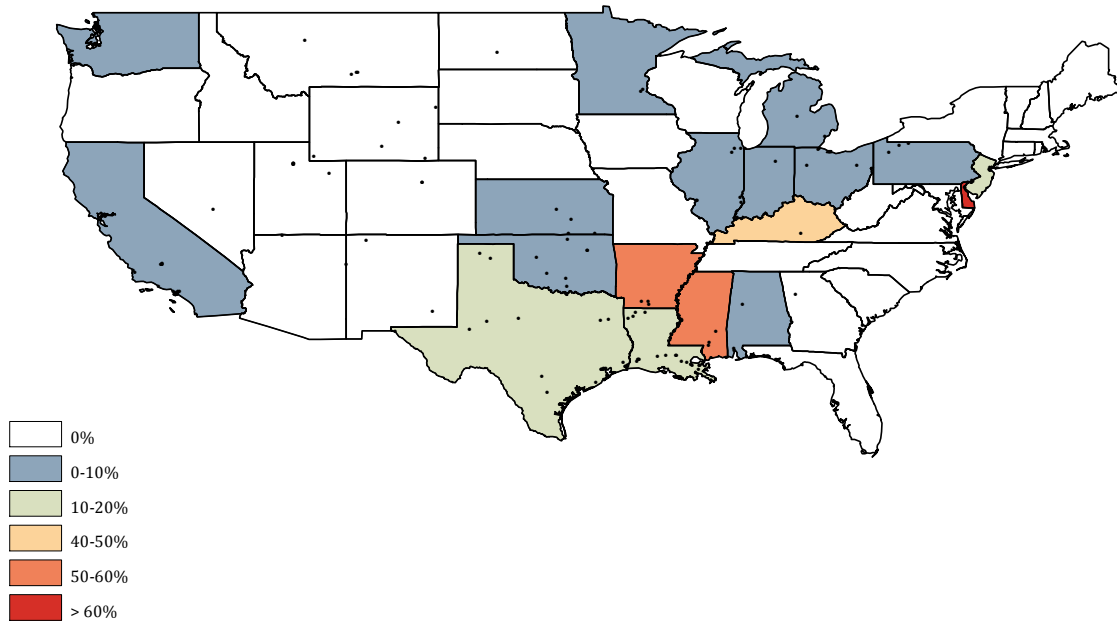

Figure B.5: Crack Spread and Average Refiner Crude Cost

Note: The crack spread is calculated as the difference in cost between a barrel of crude and a representative mix of typical outputs. For example, a simple version (the 2-1-1) is calculated as the difference in cost of 2 barrels of crude and a barrel of gasoline and a barrel of heating oil/diesel. Here I use the 6-3-2-1 crack spread, which is the difference in the total cost of 6 barrels of crude and outputs of 3 barrels of gasoline, 2 barrels of heating oil/diesel, and 1 barrel of residual fuel oil. Trends are the same for each of the four standard spreads. Source: EIA.

Notes: This table provides sample statistics on the refinery-owners that are publicly-listed. Columns 1-6 are calculated using refinery-level observations on monthly Saudi imports and crude prices and annual refinery capacity reports from the EIA. Columns 5 and 6 indicate the number of unique refineries that were owned by the company during the policy period and the number of these that received any amount of Saudi crude during the period. Total refining profits is the sum of the annual operating profits variable for refining operations from the Compustat Business Segments data, and total net income is the sum of the quarterly net income entries from the Compustat aggregation of the SEC-10K filings. Column 8 reports the ratio between the value of discount receipts relative to total refining profits. All dollar values are billions of real 2000 USD.

Notes: This table reports annual average values for contributions by refining companies to Members of Congress. The left panel reports statistics on the non-zero entries in the dataset, e.g. the size of an annual contribution conditional on a contribution being made by that company to that politician in a given year. The right panel reports statistics on the entire annual company by politician sample, including zeros for years in which the politician was a Member of Congress and the company existed but no contribution was made. The last row of the table gives annual averages by company. Contribution values are in 2000 USD.

Notes: This table shows the results from the regression of annual politician by company level political contributions on the interaction of company discount values with politician characteristics. All regressions include politician by company and year fixed effects and controls for committee membership and discount value. Discount value in billions of 2000 USD, contributions in 2000 USD. Standard errors are clustered at the year and politician by company level using the two-way clustering technique from Cameron, Gelbach, and Miller (2011).
